Objectives

- Explore patterns of pain medication administration in the perioperative period for surgical patients.

125 Million Opioid Prescriptions

US Population Filled an
Opioid Rx

Prescribed by a Surgeon

51M+ Americans undergo surgery annually

Majority expose to opioids perioperatively

Guidelines recommend multimodal analgesic approaches

“utilizing a combination of different analgesic medications and techniques, including non-opioid pain relievers like **acetaminophen** and **NSAIDs**, along with **regional anesthesia** techniques”

ASA GUIDELINES

Perioperative Benefits of Multimodal Approach

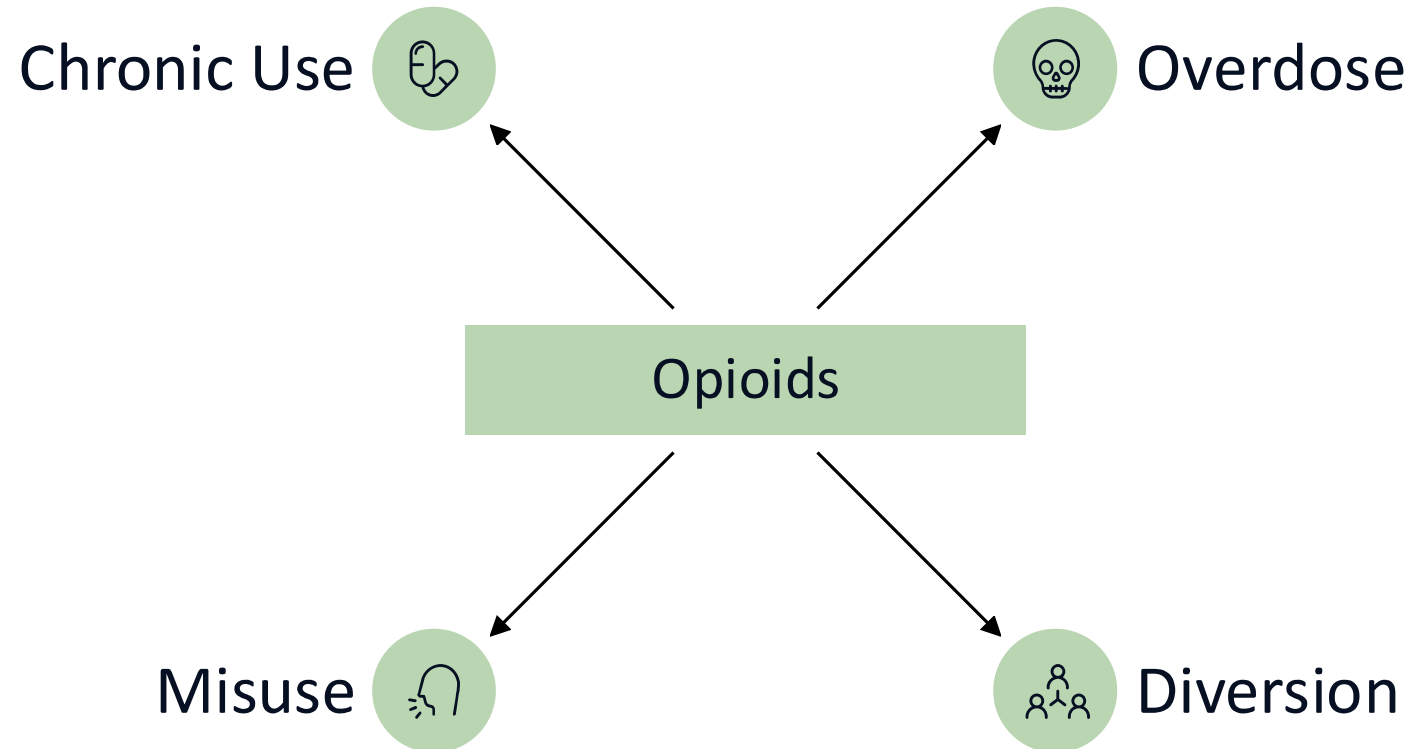

Improves pain control

Reduces opioid related side effects

Reduces length of stay

What Remains Unknown?

What pain medications are surgical patients receiving perioperatively?

What variation exists?

AIMS

Identify types of pain medications used for common surgeries

Investigate factors associated with multimodal utilization

Data Source

- Standardized Data File
- 2019-2022

Institutional Trends

Multimodal Administration by Institution

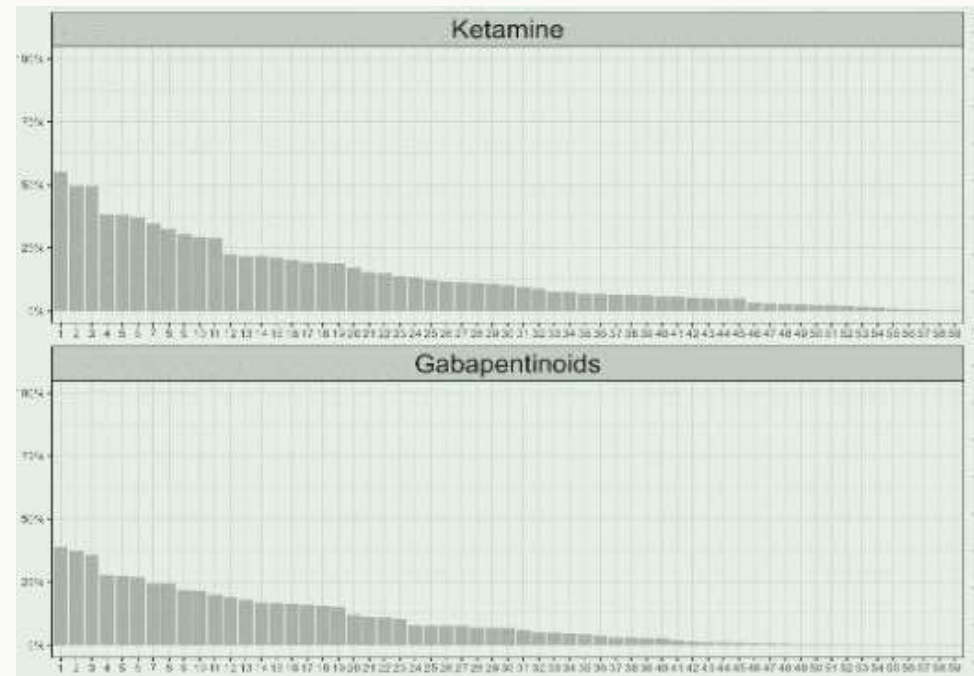

Medication Administration by Institution

Medication Administration by Institution

Institution

Institution

- We used a **mixed effects model** to account for institutional-level variation in multimodal analgesia.
- Essential when data are nested into groups, such as institutions.

Key Findings

Patient-Level Factors

All comorbidities (Liver Disease, CKD, DM, CHF, CAD, Chronic Pulmonary Disease, Cardiac Arrhythmia) were significantly associated with **increased odds of opioid-only use**.

ASA Class 4: Strongest patient level predictor of opioid-only use (OR 2.74 [2.25–3.34])

Procedure-Level Factors

Simple mastectomy: Increased odds of opioid-only (OR 16.54 [95% CI 14.30–19.14])

Total knee arthroplasty: highest odds of 3+ multimodal (OR 6.27 [95% CI 5.93–6.62])

Provider Team Factors

Attending + resident or fellow: Lower odds of opioid-only (0.91 (95% CI 0.84–0.99)); higher odds of 3+ multimodal (1.22 (95% CI 1.17–1.27))

Attending + CRNA: Lower odds of opioid-only (OR 0.88 (95% CI 0.82–0.95)); higher odds of 3+ multimodal (OR 1.16 (95% CI 1.12–1.21))

Temporal Trends

By **2022**, the odds of opioid-only use was significantly lower compared to 2019 (OR 0.56, 95% CI 0.52–0.60).

3+ multimodal analgesia use shows a **marked increase over time**, with each year demonstrating progressively higher odds compared to 2019.

Even after adjusting for these variables, **institutional variation in multimodal utilization remained.**

Institutional Variation in Analgesia Use (Adjusted Model)

Institution

Mechanisms for Variation

Provider Preference and Training

Institutional Protocols and Guidelines

Access to Medications

Perceived Efficacy and Safety Concerns

Institutional Cultural Factors

Time and Workflow Constraints

Strengths and Limitations of Institutional MPOG Data

Data Source

Robust, EHR >80 institutions

Data Granularity

High data granularity, limited to perioperative time-period

Generalizability

High, multiple hospital settings

Ease of Access

IRB approval, PCRC application process, ~6 months

Ideal Use Case

Very broad, retrospective, prospective.

Data Accuracy

High, data extraction process, MPOG constantly collaborates to improve quality.

Final Thoughts

- **Variability exists in perioperative multimodal analgesia practices.**
- **Opportunities exist for improvement:**
 - Assessment of multimodal protocol adoption
 - Investigate high and low utilizing institutions
 - Institutional benchmarking
